

MD-100 Windows Client

Module 02: Configure authorization and authentication

© Copyright Microsoft Corporation. All rights reserved.

Module Agenda

Explore authentication

Manage users and groups

Configure user account control

Implement device registration

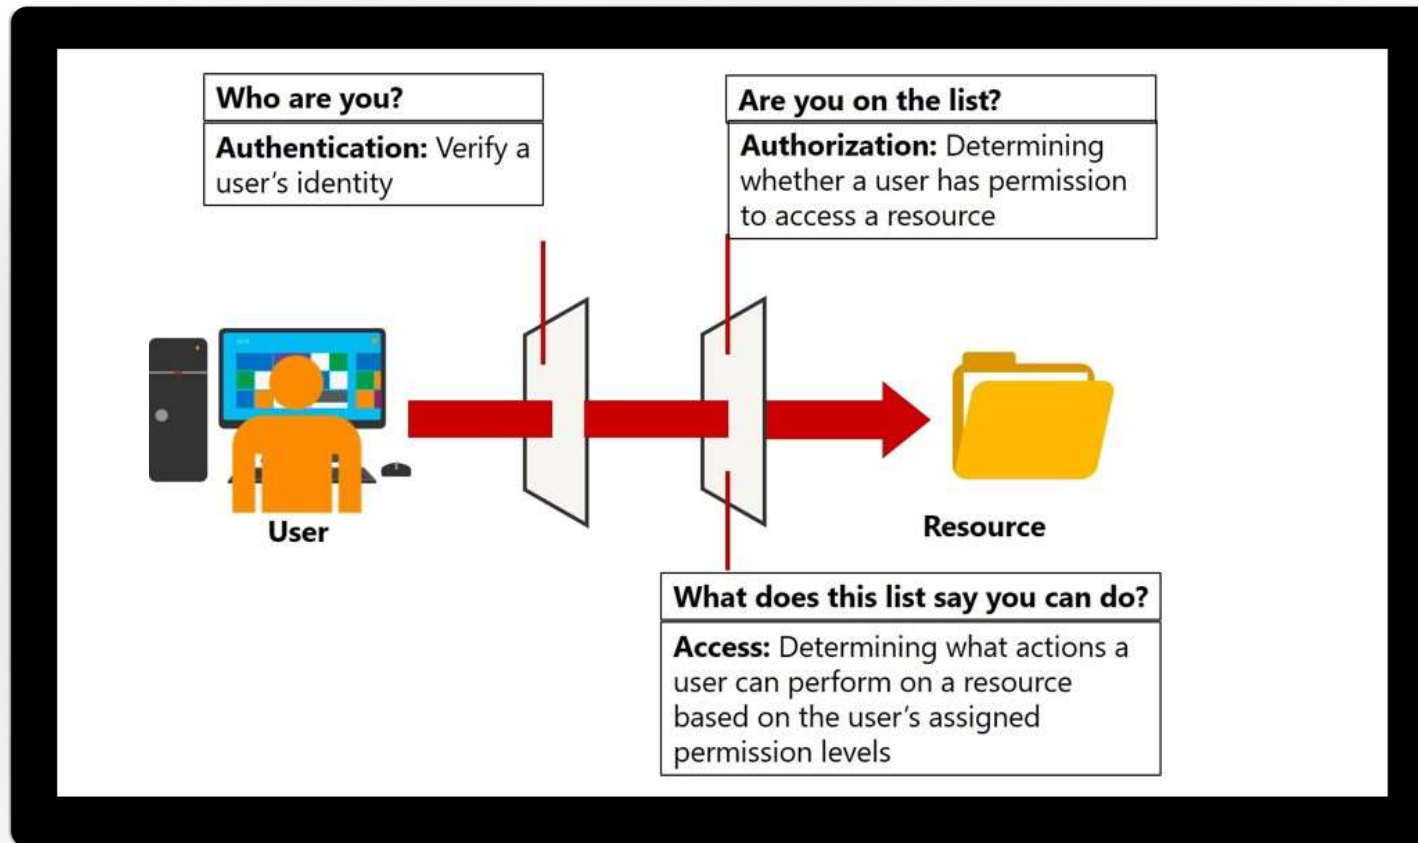

Lesson 1: Explore authentication

Lesson 1: Explore authentication

- Explore authentication and authorization
- Explore user account types
- Manage local users and groups
- Explore domains and workgroups
- Explore Credential Manager
- Explore Windows Hello
- Configure password policies and user properties
- Explore user profiles and their contents

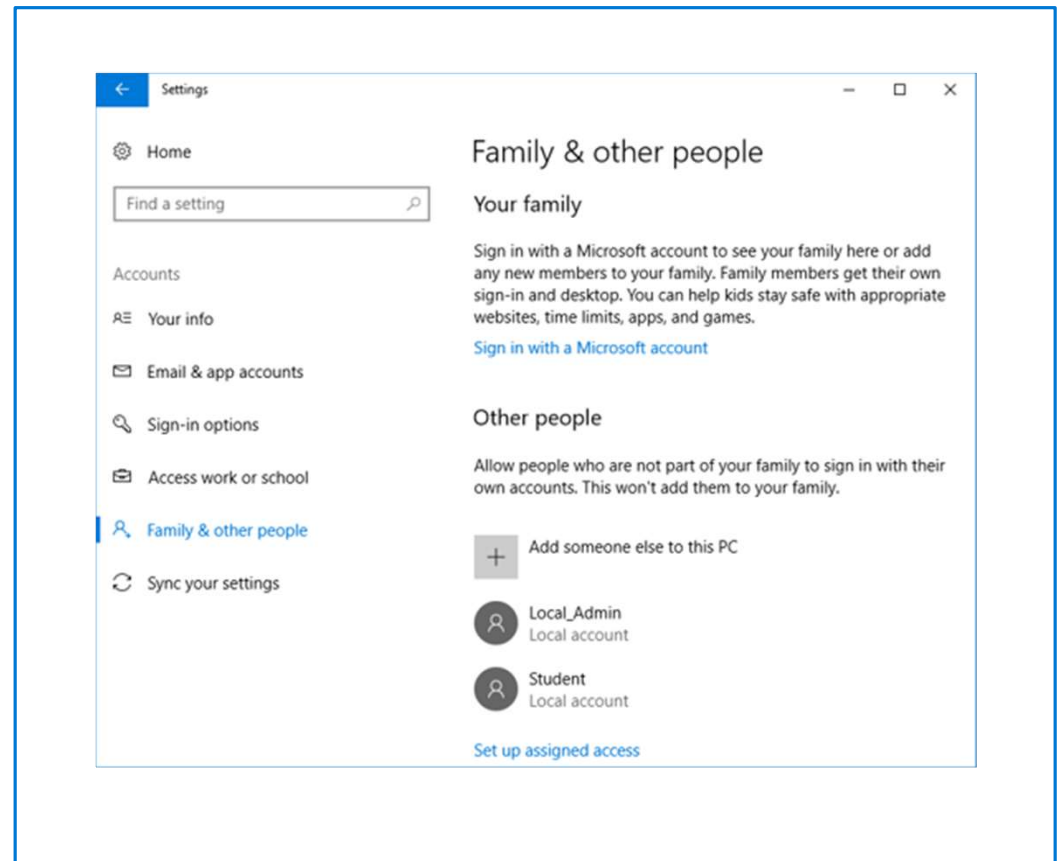

Explore authentication and authorization

Explore user account types

Windows supports the following types of user accounts:

- Local accounts
- Domain accounts
- Microsoft accounts
- Azure AD accounts

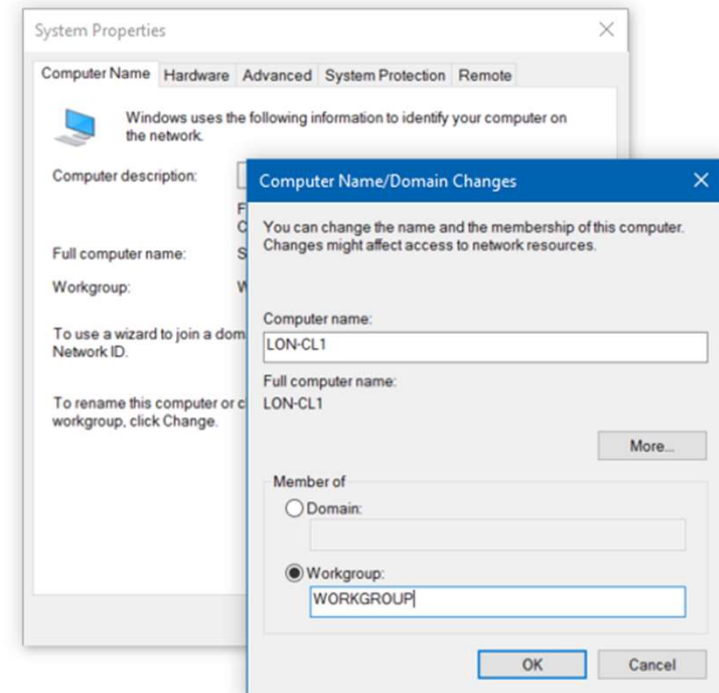

Manage local users and groups

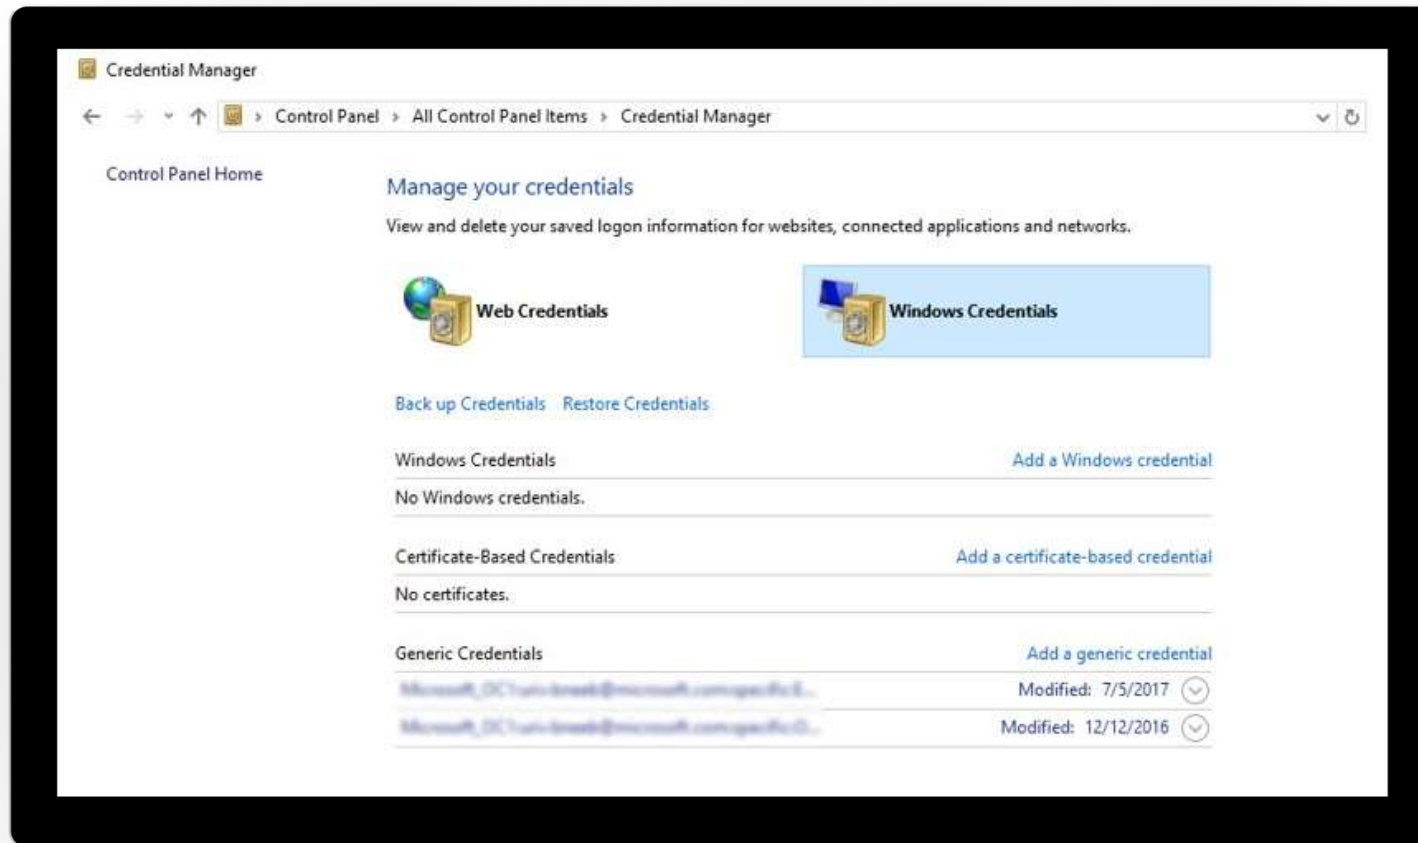

- Default local user accounts
- Default local system accounts
- Managing users
- Using account groups

Explore domains and workgroups

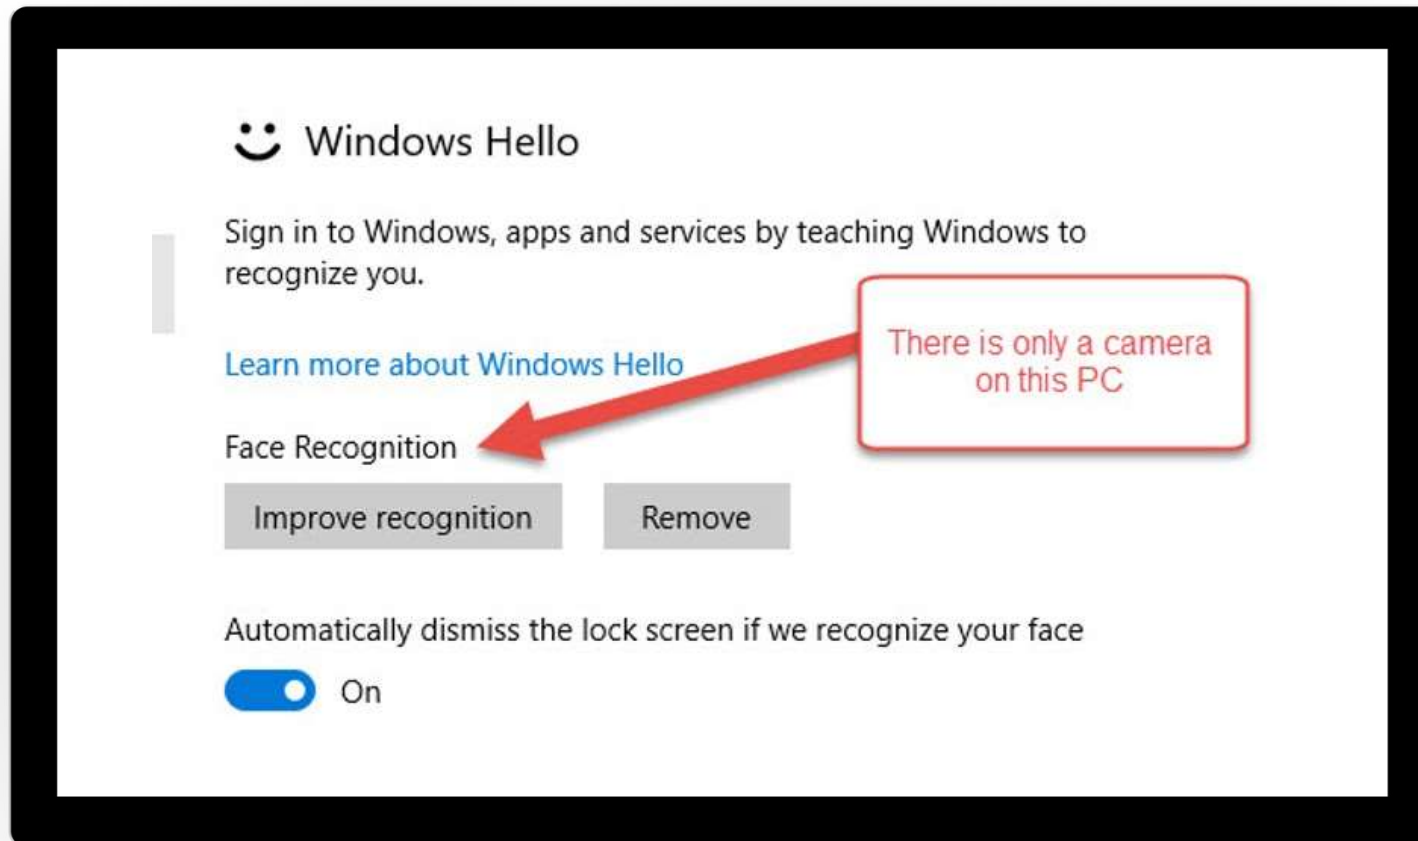

- Workgroup
 - Peer-to-peer
 - No centralized management
 - Max 20 computers
- Domain
 - Centralized Management
 - Hierarchical
 - Scalable
 - Information stored in a replicated database

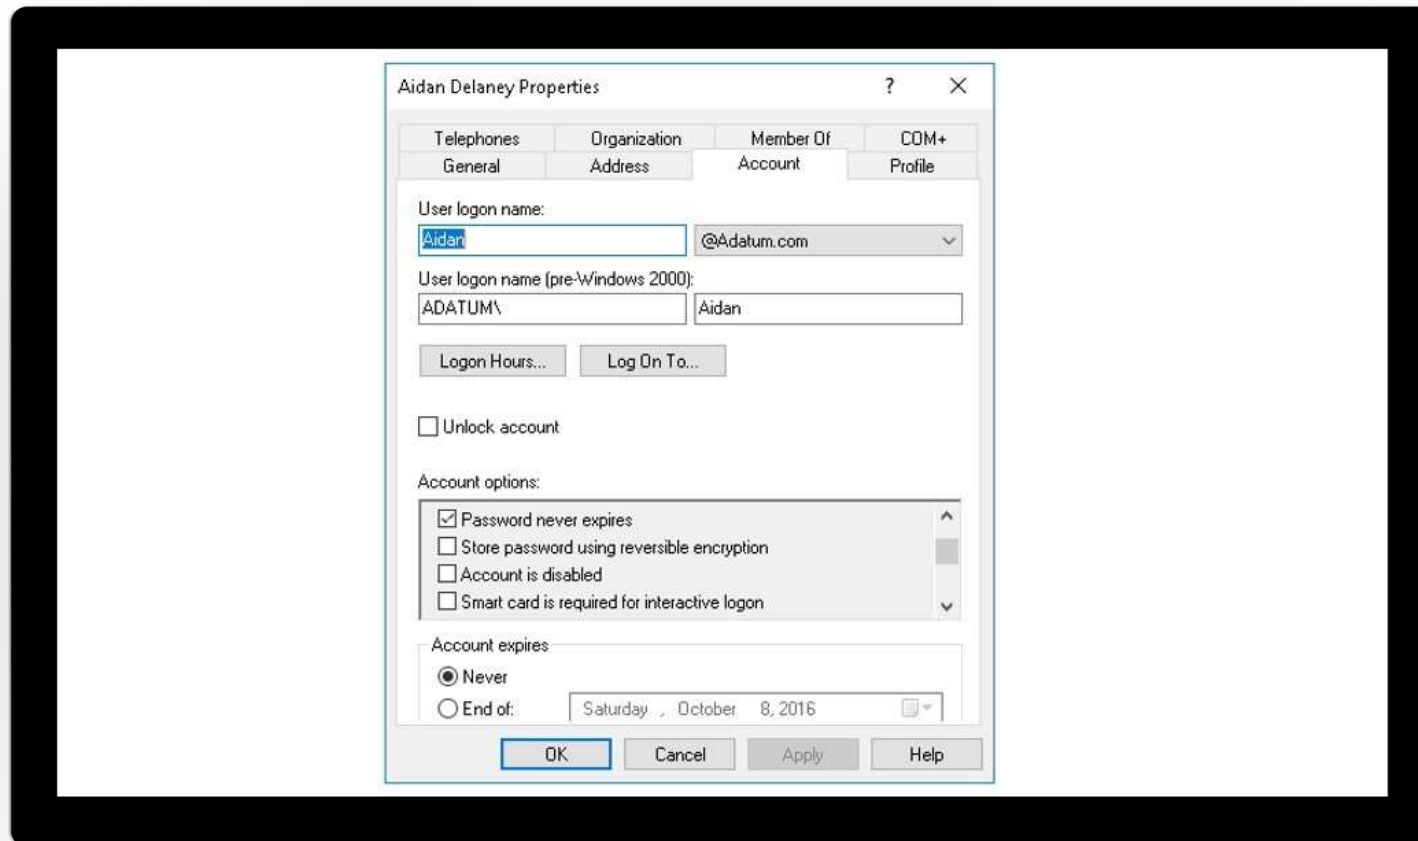

Explore credential manager

Explore Windows Hello

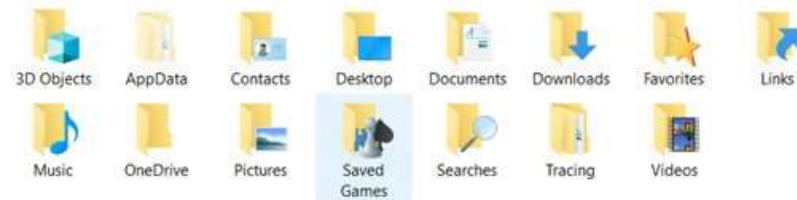

Configure password policies and user properties

Explore user profiles and their contents

User Profiles and Their Contents

- User profiles:
 - Contain user-specific settings
 - Are stored in C:\Users by default
- Include:
 - Registry settings
 - Folders, including:
 - AppData, Desktop, Favorites, Documents
- Public profile contents are included for all users

Lesson 2: Manage users and groups

Lesson 2: Manage users and groups

- Explore Active Directory
- Compare Active Directory Domain Services and Azure Active Directory
- Sign in to a domain
- Manage users and groups using Active Directory

Explore Active Directory

- Active Directory Domain Services (AD DS)
 - Hosted on a Windows Server domain controller
 - Manages user and group accounts
 - Provides identity and authentication services to domain devices and shared resources
- Azure Active Directory (Azure AD)
 - Cloud-based, no infrastructure
 - Manages user and group accounts
 - Facilitates identity and authentication services to domain and non-domain devices and services
 - Can integrate with AD DS

Compare Active Directory DS and Azure AD

Active Directory Domain Services

- On-premises, hosted on domain controllers
- X.500 hierarchical structure
- Apply configurations using GPOs
- Query using LDAP
- Kerberos authentication

Azure Active Directory

- Cloud-based, requires no server deployment
- Flat structure (no OUs)
- Query using REST APIs
- HTTP/S authentication

Signing in to a Domain

- Active Directory Domain Services (AD DS) Authentication
- Azure AD Authentication
- Troubleshooting sign-in issues
 - Connectivity
 - Name resolution
 - Domain controller
 - Synchronization issues

Manage users and groups using Active Directory

- Active Directory groups
 - Distribution groups
 - Security Groups
- Active Directory default security groups
 - DnsAdmins
 - Domain Admins
 - Domain Computers
 - Domain Users
 - Enterprise Admins
 - IIS_IUSRS
 - Print Operators
 - Remote Desktop Users

Lesson 3: Configure user account control

Lesson 3: Configuring User Account Control (UAC)

- Explore User Account Control
- Examine how UAC works
- Understand UAC elevation prompts
- Configure UAC notification settings

Explore User Account Control

UAC is a security feature that simplifies the ability of users to run as standard users and perform typical tasks:

- UAC prompts users for administrative credentials if the task requires administrative permissions
- You can configure how much control the user has over the UAC prompting experience.

Examine how UAC works

In Windows, what happens when a user performs a task that requires administrative permissions?

Standard users:

UAC prompts the user for the credentials of a user with administrative permissions

Administrative users:

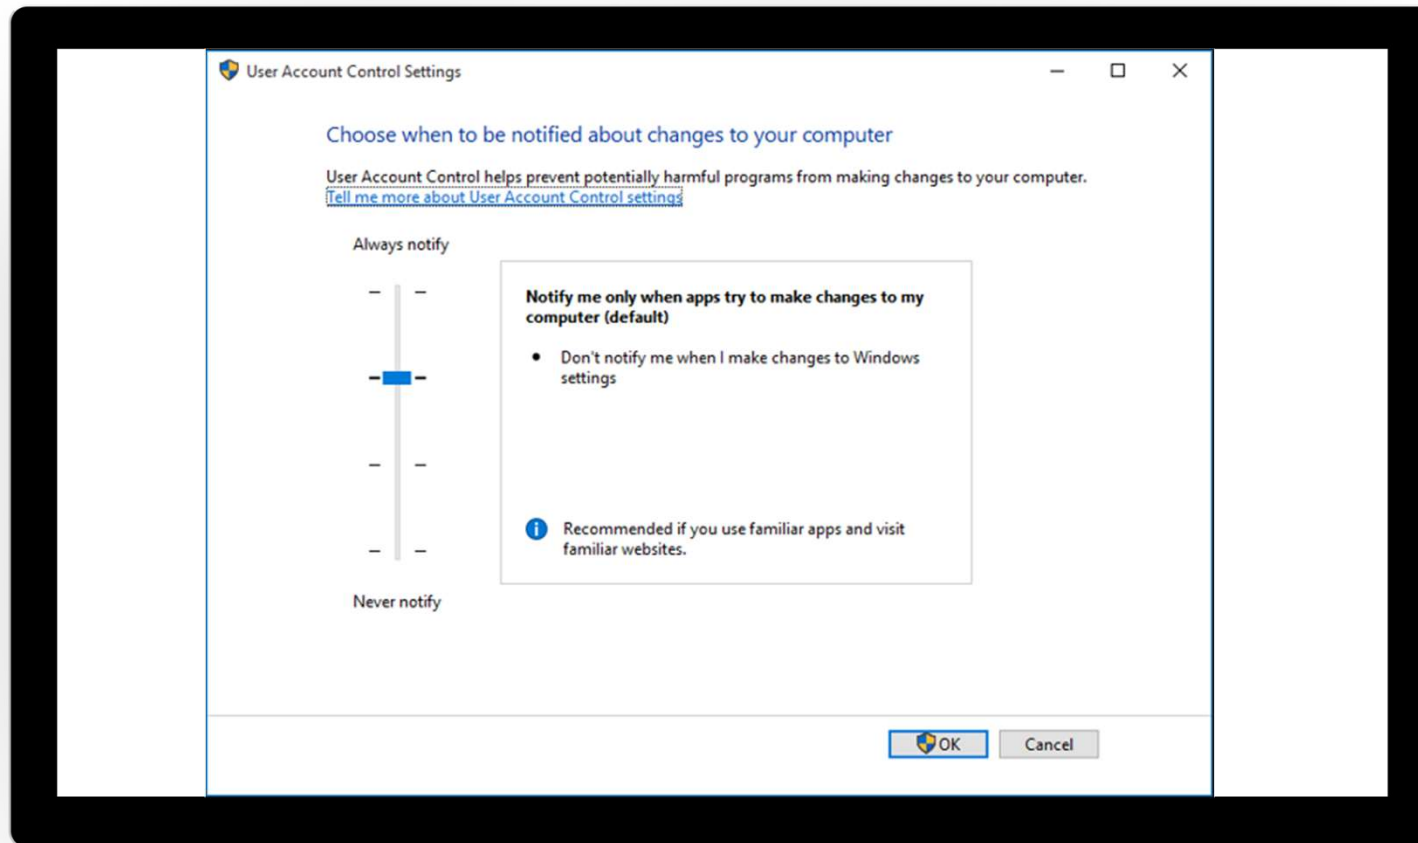

UAC prompts the user for permission to complete the task

Understand UAC elevation prompts

Tasks that require UAC elevation:

- Install/uninstall applications
- Install a device driver
- Configure Windows updates
- Configure parental controls
- Change Windows Firewall settings
- Change a user's account type
- Modify UAC settings
- Configure Remote Desktop access
- Add or remove a user account
- Copy or move files into the Program Files or Windows directory
- Schedule automated tasks
- Restore system-backup files
- Browse to another user's directory

Configure UAC notification settings

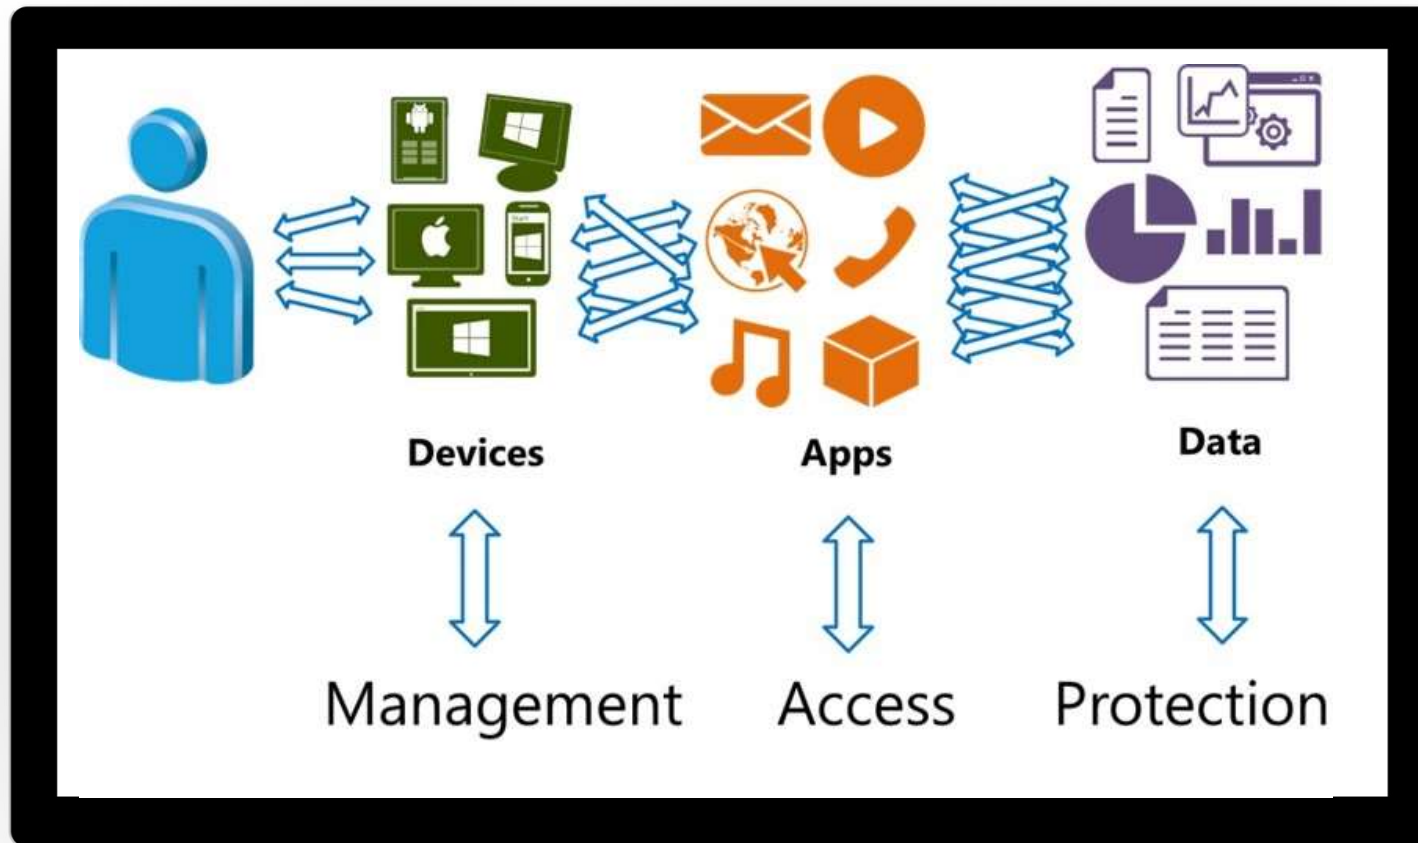

Lesson 4: Implement device registration

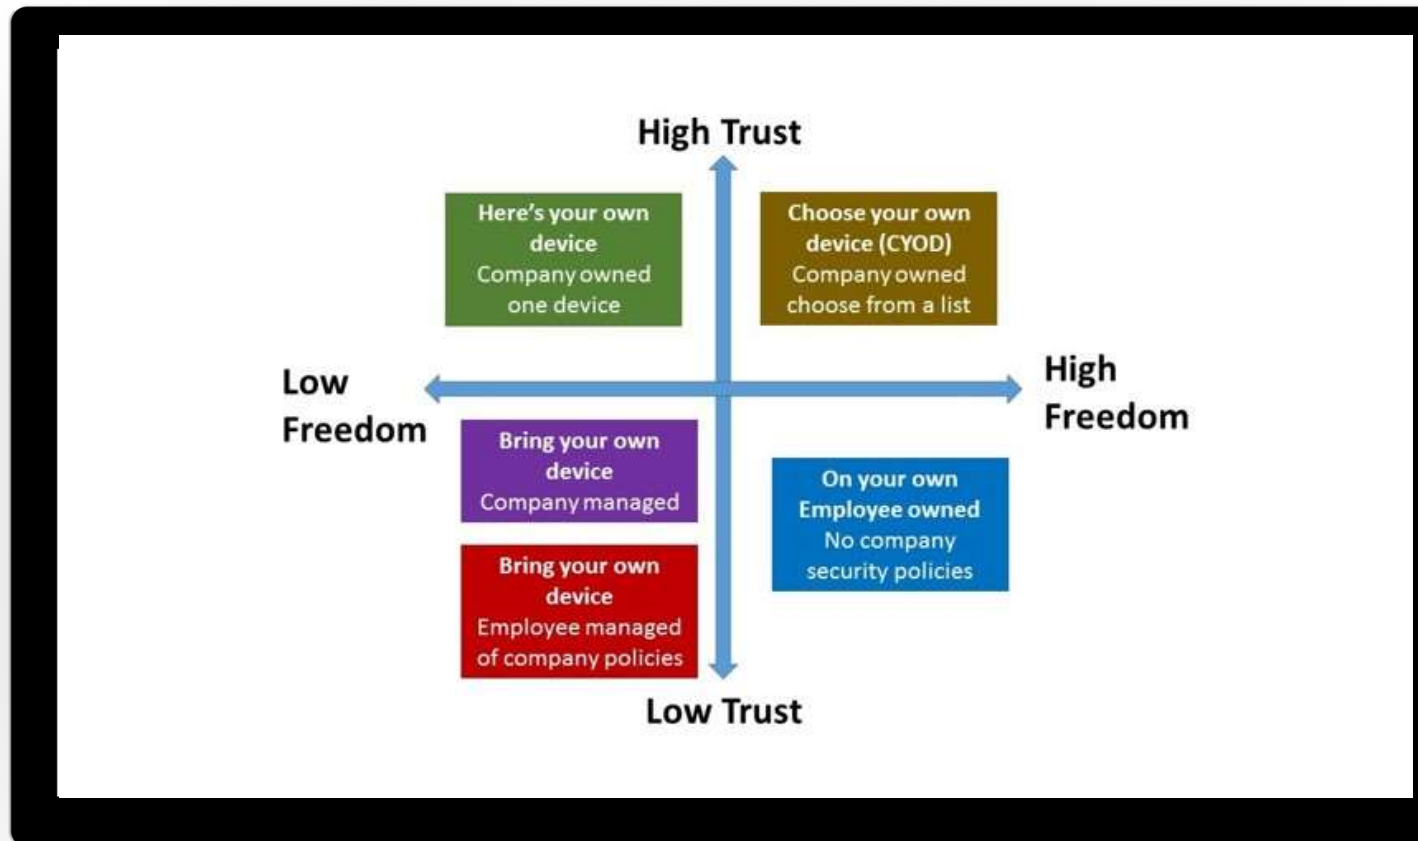

Lesson 4: Implement device registration

- Understand the challenges to data access for multiple device types
- Explore the Microsoft device strategy framework
- Explore device registration
- Examine how device registration works
- Assess infrastructure requirements to support device registration
- Register and enroll devices

Understand challenges to data access for multiple device types

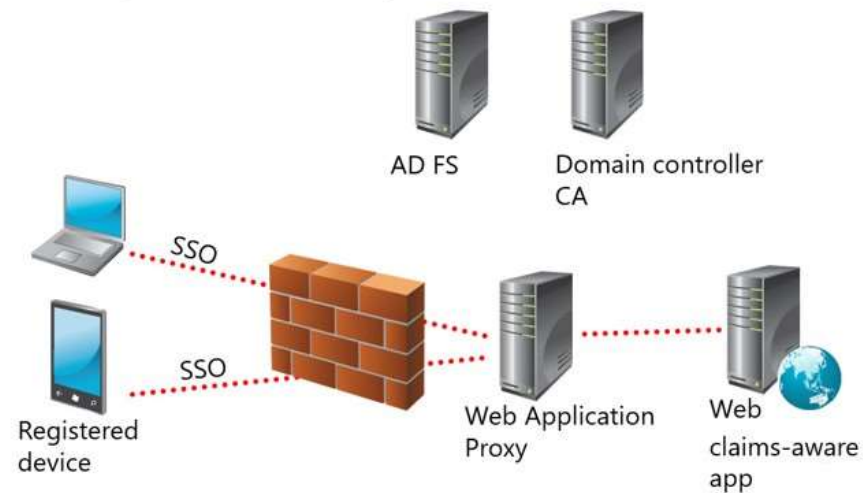

Explore the Microsoft device strategy framework

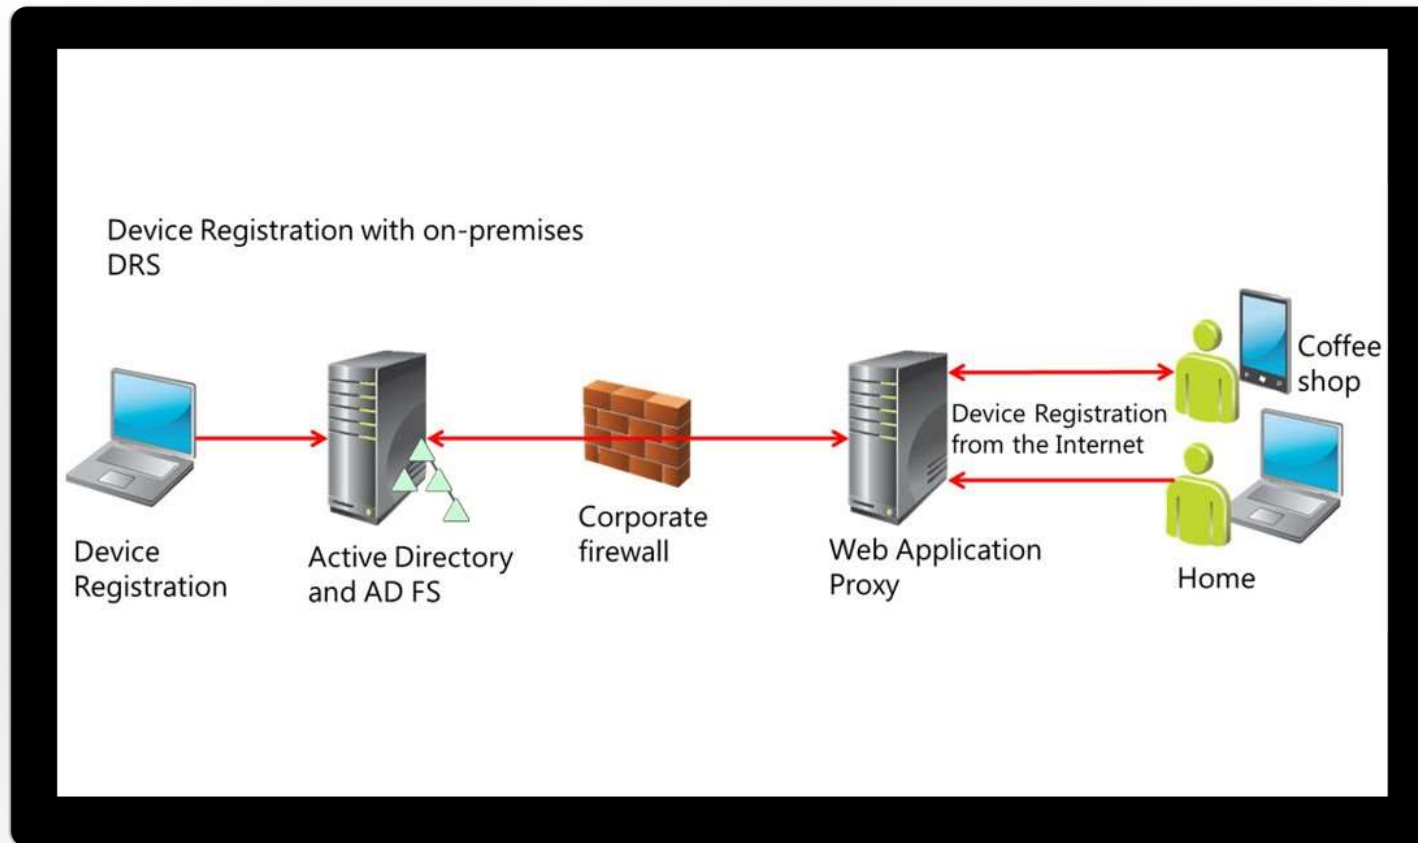

Explore device registration

Overview of Device Registration

Access internal websites and company apps without entering credentials every time

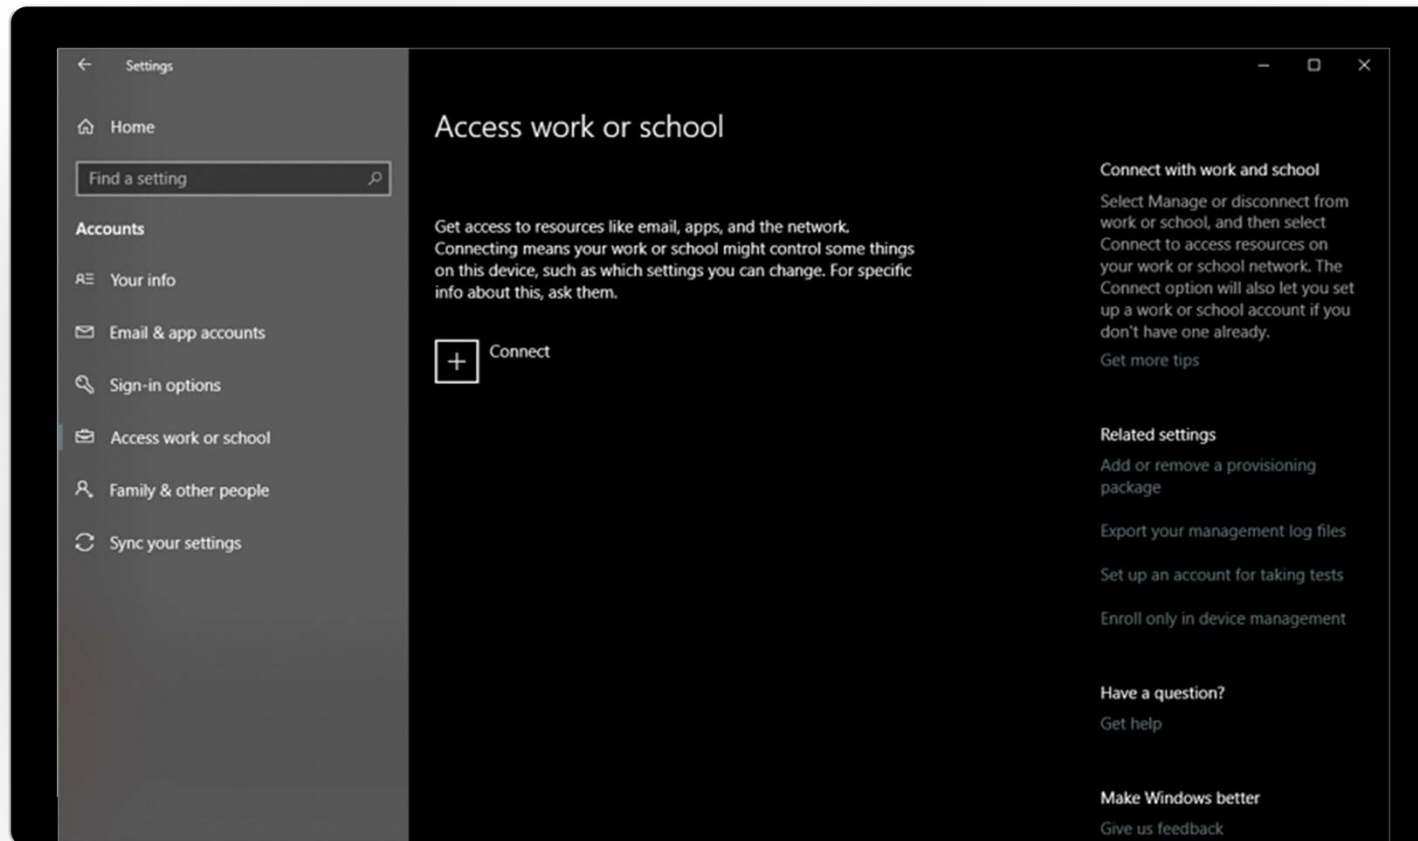

Examine how device registration works

Assess requirements to support device registration

- Active Directory environment
- AD FS
- Public key infrastructure (PKI)
- Device Registration Service
- A DNS record for the host named *Enterpriseregistration*.
- Web Application Proxy.
- A supported operating system on the device.

Register and enroll devices

Practice Labs

Managing Local User and
Microsoft Account
Authentication

Managing Domain
Authentication

Managing password and
account options

Troubleshooting Domain
Authentication

Module Review

Explore authentication

Manage users and groups

Configure user account control

Implement device registration
